FOREWORD

This report was prepared by the Aerospace Sciences Laboratory of the Lockheed Missiles and Space Company, Sunnyvale, California. It presents the documentation for a digital computer program known as PRESTO II. This program was developed by Lockheed for the Langley Research Center under NASA Contract NAS 1-5255. A FORTRAN source deck listing included with the master copy of this report completes the program documentation. PRESTO II makes use of computer subroutines that were developed for PRESTO (Program for Rapid Earth-to-Space Trajectory Optimization) under NASA Contract NAS 1-2678. This report does not include any information on those subroutines that were described in the PRESTO final report.

R. C. Rosenbaum was responsible for the work reported here. Computer programming was performed by Miss Zoe Taulbee.

Results of the program carried out under Contract No. NAS 1-2678 have been published as NASA CR-158 entitled "Program for Rapid Earth-to-Space Trajectory Optimization" by Robert E. Willwerth, Jr., Richard C. Rosenbaum, and Wong Chuck.

PRECEDING PAGE BLANK NOT FILMED.

ABSTRACT

A high-speed computer program for trajectory optimization has been developed. Program speed is obtained through the use of an approximate analytic solution to the three-dimensional equations of motion on a "cylindrical" Earth. The thrust attitude control history is assumed to follow the "linear-tangent" law. The method of steepest descent is used to determine the control parameters that maximize payload while simultaneously satisfying terminal constraints.

1. INTRODUCTION

The development of the high-speed digital computer has made it possible to apply sophisticated numerical techniques to the problem of trajectory optimization. The steepest-descent method, in particular, has been used quite successfully to evaluate the performance of rocket boosters. For preliminary design studies, however, where a great many configurations must be evaluated, conventional numerical methods may require an excessive amount of computer time. Most of this time is taken up by repeated integration of numerous differential equations.

In PRESTO II, most of the numerical integration is eliminated through the use of an approximate analytical solution to the equations of motion. The pitch and yaw components of the thrust attitude history for the upper stages are made up of one or two segments which follow the linear-tangent rule, i.e., the tangent of the attitude angle is equal to a + bt. The first stage is assumed to fly at zero angle of attack. An iterative procedure, employing the steepest-descent method, is used to find the values of the controls which meet terminal constraints and maximize payload. In addition to the thrust attitude history, the controls that can be optimized are the initial flight path angle and azimuth, the launch time, the length of a coast between two powered stages, and the cutoff and ignition times for a restartable final stage.

It is known that the linear-tangent law provides an optimal solution to the ascent problem if one makes a "flat-Earth" assumption. Furthermore, a closed-form solution to the equations of motion is available for the "flat-Earth" case. In PRESTO II, the Earth is represented by a cylinder. The

equations of motion in the pitch plane include the centrifugal and Coriolis accelerations. Lateral motion is assumed to be uncoupled from the pitch-plane motion. The linear-tangent law is applied to a thrust attitude angle that is measured with respect to the local horizontal rather than a fixed direction.

The trajectory of the first stage of the booster vehicle is integrated numerically. The first stage trajectory is a function only of the initial flight path angle and launch weight because of the zero angle of attack assumption. A table of trajectory variables at the end of the first stage as a function of flight path angle is formed. This table is then used to represent the first stage during the optimization process.

After an optimum trajectory has been obtained on PRESTO II, the optimum controls are used to run a numerically integrated trajectory on PRESTO. Terminal conditions will, in general, not be satisfied because of the approximations in the closed-form solution. A backward guidance run and a final guided run are then made on PRESTO to produce a numerically integrated trajectory which meets terminal conditions and provides a near-optimum payload.

A description of the program, together with flow diagrams for the larger subroutines, is presented in Section 2. The nomenclature introduced in the PRESTO II subroutines is defined in Section 3. Section 4 serves as a manual for operating the program. The optimization equations are derived in Section 5 and Section 6 provides a derivation of the approximate solution to the equations of motion.

PRESTO II makes use of the nomenclature and logical arrangement of PRESTO to as great a degree as possible. It is therefore suggested that the reader have the PRESTO final report available for reference.

2. PROGRAM DESCRIPTION

PRESTO II is written in the Fortran IV language. The program is composed of two distinct parts. One part is the DELTA version of the original PRESTO program with a few subroutines altered. The other part is composed of the new subroutines associated with PRESTO II. In this section, the two parts of the program will be referred to as PRESTO and PRESTO II.

PRESTO II is comprised of the following subroutines:

MAIN	CONVRT
STAGE 1	TAULAY
PERTRB	TOOK 5
TRAJ 2	OPCNL 2
NSTOP 2	RUNGEK
COAST 2	NTEGRT
CONC	LIFT
MEQ 2	EQUATN

The following subroutines are taken from the PRESTO program:

PRESTO (MAIN of PRESTO)	MISCON *
TRAJ	SYMVRT *
PCAL	TOOK *
OPCNL	INER *
MEQ	ATMOS *
INSTOP	LUNEPH *
ICS	PLANEP *
DEQ	REIN *
COAST	OPTION *
RKAD	WIC *

The function of each of the PRESTO II subroutines is discussed here.

Subroutine Functions

MAIN

The operations performed in the PRESTO II MAIN program are similar to those performed in the PRESTO MAIN program. Additional calculations are made to set up the initial values of the control and vehicle parameters. The closed-form lift-off calculation has been removed to a separate subroutine. At the end of the PRESTO II iterations, subroutine PRESTO is called to begin the numerical integration of the trajectory.

STAGE 1

The trajectory for the first stage of a vehicle launched from the Earth's surface is computed here. A table of trajectory variables at the end of the first stage, as a function of the initial flight path angle, is stored in the two dimensional array, GTABLE. At the beginning of each case, two entries are made in GTABLE. The first is for the initial flight path angle, $\gamma_{\rm I}$, and the second is for $\gamma_{\rm I}$ plus DEIGAM. The slope of the trajectory variables is then computed and stored in GGTABL. Thereafter, new entries in GTABLE and QGTABL are made only when the initial flight path angle falls outside of the region already included in the table. There is room for twenty-five entries on each side of the initial table entry.

If the fixed-final stage option is being used, so that the launch weight is adjustable, the influence of launch weight changes must also be determined. Initially, this is done by perturbing the launch mass by .001 times the initial mass. The change in the first stage burnout conditions due to this mass change is stored in the OKMS array. There is an entry in OKMS for every entry in GTABLE. Thus, every initial flight path angle has a mass slope associated with it. Furthermore, for every table entry, the launch mass is stored in the array GMASS. When a table lookup is made, the current launch mass is compared with the GMASS associated with the current flight path angle. This mass difference is multiplied by the current value of the mass slope, OKM 1, to obtain the correction in first stage burnout conditions due to the change in launch weight. A new mass slope is computed after NEWKM 1 entries have been made in GTABLE. NEWKM 1 is input by the user.

The same sort of correction is made if the launch azimuth is adjustable. The current value of the azimuth slope is stored in the second half of OKM 1. A new slope is computed whenever the initial azimuth changes by more than DELPSI. DELPSI is also input by the user.

The trajectory variables at the end of the first stage are placed in Fl and are returned to the calling program by means of an argument list.

A flow chart for STAGE 1 is at the end of this section.

PERTRB

The sensitivities of the terminal constraints and stopping parameters to changes in the control variables are computed here. PERTRB replaces the backward integration performed in PRESTO. Each of the controls is perturbed by an amount, DELCON, set by the user. A trajectory is then computed. The perturbed terminal conditions are compared with the nominal terminal conditions to determine the influence of the control change.

A flow chart for PERTRB is at the end of this section.

TRAJ 2

TRAJ 2 performs the same operations as does TRAJ in PRESTO. TRAJ 2 is considerably smaller than TRAJ because of the absence of a backward trajectory. The subroutine has also been shortened through the use of a common area for determining the trajectory during each stage.

A flow chart for TRAJ 2 is at the end of this section.

NSTOP 2

This subroutine interpolates to the correct stopping parameter.

COAST 2

Motion across a coast stage is determined here. The equations used are from the COAST routine in PRESTO.

CONC

The control variables to be used on the next trajectory are computed.

MEQ 2

The matrices required to compute the control changes in CONC are computed. See Section 5 for a derivation of the equations used.

CONVRT

The trajectory variables associated with the cylindrical coordinate system are converted to the geographic coordinates used in PRESTO. The equations used are given in Section 6.

VALUAT

The derivatives used in the numerical integration of the first stage are computed.

LOOK 2

This routine is similar to LOOK. It provides the linear interpolation used in STACE 1.

OPCNL 2

The trajectory variables at the beginning and end of each stage are output.

RUNGEK

This subroutine provides the numerical integration formulas used for the first stage. It is similar to RKAD.

NTFGRT

The integration of the first stage is controlled.

LIFT

The closed-form lift-off calculation is performed.

EQUATIN

The approximate analytic solution to the equations of motion is computed.

The results are stored in the array, UVH, and are returned to the calling program through an argument list.

The following PRESTO subroutines have been changed.

PRESTO

PRESTO is the subroutine name for the MAIN routine of the PRESTO program. The initial setup operations now appear in the PRESTO II MAIN and have been removed from subroutine PRESTO. When the program is under the control of PRESTO, it runs a nominal trajectory, a backward guidance trajectory, and a final guided run. Control is then returned to the MAIN program.

TRAJ

A change has been made so that an intermediate constraint (circular park orbit or radius of perigee) will be applied on the final guided run if it was used in PRESTO II.

PCAL

The thrust attitude angles are computed from the PRESTO II angles on the nominal trajectory. This computation replaces the table look-up in PRESTO. The equations used here are derived in Section 6.

REIN and WIC

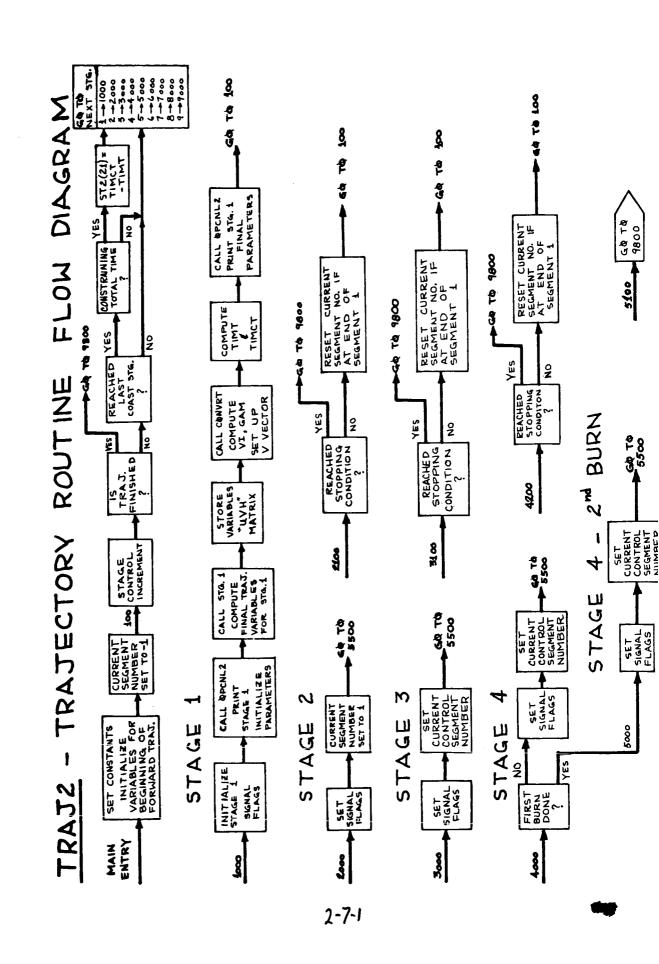

Changes associated with the PRESTO II data requirements have been made.

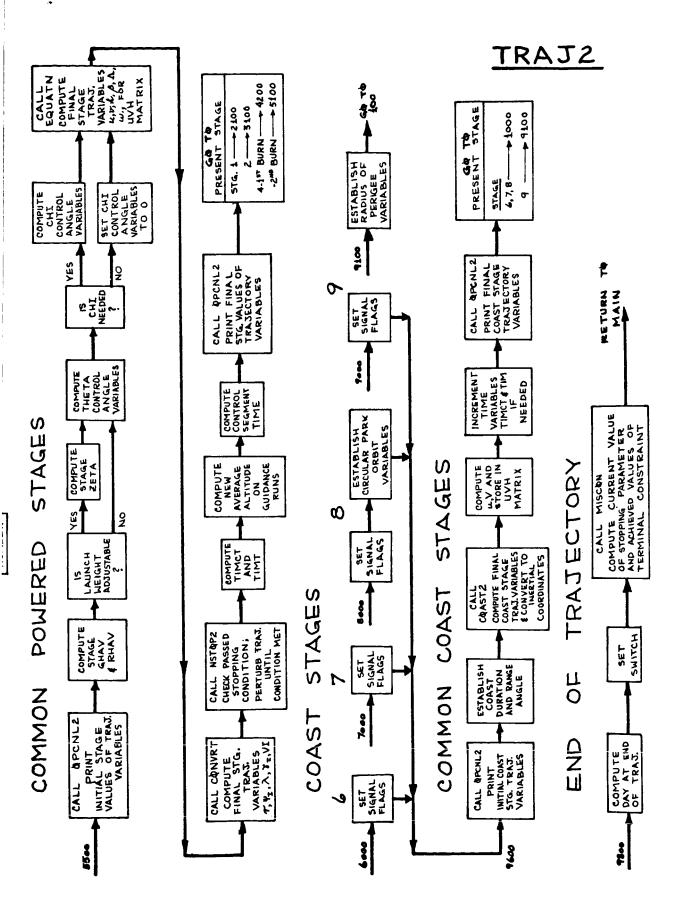

Use of PRESTO II Without PRESTO

If a numerically integrated trajectory is not required, the size of the program can be greatly reduced by eliminating many of the PRESTO subroutines. PRESTO II can run by itself using all of the PRESTO II subroutines plus those PRESTO subroutines identified by an asterisk on page 2-1. A dummy subroutine PRESTO is also required.

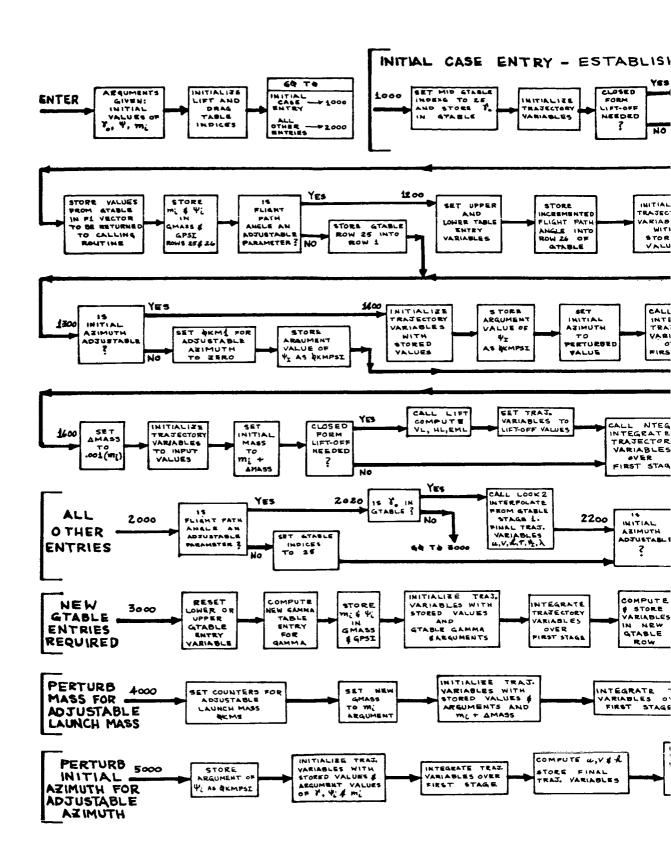

Use of COMMON Variables

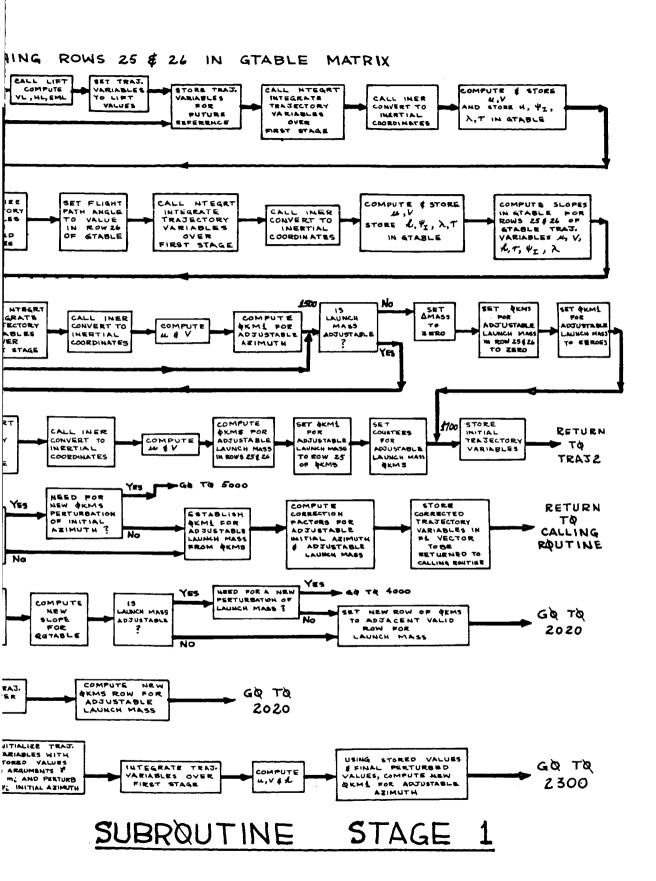

The variables stored in COMMON have been separated into three groups. One group, known as the common COMMON, is used in all subroutines that employ COMMON. A second group of variables which are used only in PRESTO II subroutines appears at the end of common COMMON in the PRESTO II subroutines. A third group of variables which are used only in the PRESTO subroutines appears at the end of common COMMON in the PRESTO subroutines.

3. DEFINITIONS OF PRESTO II VARIABLES

The variables introduced in the PRESTO II subroutines are defined here.

CA	Pitch plane steady-state control angle for current stage							
CB	Pitch plane slope for current stage							
CE	Yaw plane steady-state control angle for current stage							
CF	Yaw plane slope for current stage							
CON	Vector of current values of adjustable parameters							
	3. Length of coast after first burn in stage 4							
	4. Length of first burn in stage 4							
	5. Length of coast after stage 3							
	6. Length of coast after stage 2							
	7. Length of coast after stage 1							
	8. Launch time of day							
	9. Initial azimuth							
	10. Initial flight path angle							
	11. Initial value of pitch plane control variable for segment one (a_1)							
	12. Slope of pitch plane control variable for segment one (b ₁)							
	13. Initial value of yaw plane control variable for segment one (e,							
	14. Slope of yaw plane control variable for segment one (f ₁)							
	15. Initial value of pitch plane control variable for segment two (a2)							
	16. Slope of pitch plane control variable for segment two (b2)							
	17. Initial value of yaw plane control variable for segment two (e2)							
	18. Slope of yaw plane control variable for segment two (f2)

PZETA Vector of powered stages mass ratios used by PERTRB routine for computation of perturbed trajectories

QCTABL Matrix of slopes associated with GTABLE matrix entries in STAGE 1

RHAV Vector of average radii of powered stages

SA Vector of pitch plane steady-state control angles for control segments one and two

SB Vector of pitch plane sbpes for control segments one and two

SE Vector of yaw plane steady-state control angles for control segments one and two

SECTIM Vector with values of control segment time duration up to that stage for each stage included in a control segment, with a zero stored in stages not included in a control segment

SF Vector of yaw plane slopes for control segments one and two

SF1. Vector returned by STAGE 1 routine with stage one burnout values of u, v, h, τ , ψ_T and λ

SHAV Vector of saved values of HAV vector

SOMI Vector of saved values of OMI vector

SPR Derivative of stopping parameter with respect to mass ratio

SST3 Vector of saved values of ST3 vector

STGTIM Vector of stage time duration for all stages

SWFUEL Correct fuel weight in the final stage

TABLEG Data block 43

TCOAST Time duration of a coast stage

TCTIM Total time in each control segment initially

TIM Current value of control segment time

UVH Matrix of trajectory variables u, v, h, τ , $\psi_{\underline{I}}$, β , w and Λ for initial and final values of each stage

ZETA Vector of mass ratios for each powered stage

ZINV Inverse of weighting function matrix

ZKA Matrix relating changes in terminal constraints to changes in control parameters

ZKAL Vector relating changes in terminal constraints to changes in launch mass

4. PROGRAM OPERATION

DATA INPUT FORMAT

Data Blocks

Data required for PRESTO execution are grouped and input in data blocks which are identified by number. Each block contains a common type of information such as the case title or a stage thrust table, and utilizes a specified FORTRAN format for the entire data block. The contents of each data block are discussed and then summarized on the next several pages.

Header Cards

Input data are punched on cards which are placed behind the program binary deck. Cards for each data block are preceded and identified by a "header" card. The format of the header cards is 4I3, where the first field is the data block number and the second and third fields give the (inclusive) locations within the data block that the subsequent data cards are to be placed. Thus, if the user wished to change constants 2, 3 and 4 in data block 10, the header card would be punched 10 2 4 , and the first three fields of the next card would contain the three constants. The fourth field of the header card is used to identify the vehicle stage number for the data, where necessary. The stage designation should be included only for the data blocks as specified on the following pages.

Card Sequencing

Cards within each data block must follow sequentially, but data blocks may be arranged in any order. A blank card must follow the last data card.

Successive Cases

Successive cases can be run on PRESTO with a minimum of additional data input. Only the changes in data from the preceding case must be input. A blank card must follow the data for each case.

999 Card

A card with 999 punched in the first three columns must end the data deck. It is to be placed behind the blank card which ends the data for the final case. When the READ routine encounters the 999 card, a normal stop is indicated to the machine operator, so that the job can be terminated.

DISCUSSION OF THE DATA BLOCKS

The following discussion will emphasize only the changes in the input with respect to the PRESTO input. The summary definition of the data blocks will be complete.

Data Block 4

- (4) For planar missions, optimize theta only. For non-planar missions, optimize both theta and chi.
- (11) The q-alpha constraint is no longer available. If the first stage is being used, the zero-alpha constraint is automatically applied during PRESTO II iterations and must, therefore, be specified in the input so that the final PRESTO runs will be correct. Positions 5 and 6 in data block 22 must correspond to the burn time for the first stage.
- (18) This option indicates whether or not there is a coast stage between the two control segments.
- (19) If the accuracy of a numerically integrated trajectory is not required, the program will terminate at the end of the last PRESTO II iteration.
- (20) Checkout matrices and the integration of the first stage can be output with this option.

Data Block 5

Stage 5 is no longer available. Stage 1 is always the numerically integrated stage. For orbital launches, stages 2, 3 or 4 may be used as the first stage.

Data Block 6

There is only one adjustable burn in stage 4 and only one adjustable coast can be specified. Parameter codes 1 and 2 are not available.

Data Block 8

Allow no more terminal constraints (including mass) than the number of adjustable controls.

Data Block 24

The nominal value of coast time is specified in addition to the coast angle. The program will iterate to the input time on the nominal trajectory. The input angle is an estimate of the coast angle corresponding to the desired time.

Data Block 27

The recommended weighting functions are the following:

Name	Code	Weighting Function
Coast	3,5,6,7	10-6
Burn	4	10 ⁻³
Launch Time	8	10-9 10-1
Azimuth	9	10-1
Flight Path Angle	10	500.
Initial theta in first segment	11	1.
Slope of theta in first segment	12	1000.
Initial chi in first segment	13	.1
Slope of chi in first segment	14	1000.
Initial theta in second segment	15	.1
Slope of theta in second segment	16	10 to 1000
Initial chi in second segment	17	.1
Slope of chi in second segment	18	10 to 1000

Data Block 30

Thrust must be constant except for the first stage.

Data Blocks 31, 32, 33

The only aerodynamic coefficient to be used is the drag coefficient for stage 1.

Data Block 40

The first and last values of theta for each control segment are specified. If there is no coast between the two control segments, theta must be continuous, i.e., the last value of the first segment must equal the first value of the second segment.

Data Block 41

Same as 40 for chi.

Data Block 42

The recommended value for the perturbation in the average value of a control angle is .01 radians. For a slope, the recommended value is .0001 radians/sec. If a stage is quite short, a larger perturbation should be used for the slope. The following values are suggested for the other perturbations:

Coast time	5 sec
Burn time	1 sec
Azimuth	.01 rad
Flight path angle	.001 rad

Data Block 43

DEIGAM is the separation between entries in the table for stage 1. Provision has been made for 25 entries on each side of the initial value. A value of .1 degree is sufficient for vehicles with an initial flight path angle ranging from 87 to 89 degrees. A larger value for DEIGAM can be used if the initial flight path angle is lower.

NEWKMl is the number of gamma table entries in between evaluation of a new sensitivity for launch weight perturbations. 3 is a satisfactory value for a DEIGAM of .1.

DELPSI is the change in azimuth required before a new sensitivity to initial azimuth perturbations is computed. Ten degrees is the suggested value.

Data Block 44

This data block determines the number of control segments to be used and the stages contained in each. The first number is the KK4 corresponding to the first powered stage in segment one. This is followed by the KK4's of the remaining stages in the first segment, including coasts. Six is input at the end of the first segment. If there is only one segment, a 7 follows the 6. If there are two segments, the KK4's of the stages in the second segment follow the 6 and a 7 terminates the data block.

Example: If the stage sequence in data block 5 is

16273484

and two segments are to be used with stage 8 in between the two segments, data block 44 should contain

2 9 3 4 6 5 7

Data Block 45

An expected average altitude must be input for each stage.

Changes in Program Use as Compared to PRESTO

There are several changes and limitations in the use of PRESTO II as compared to PRESTO. These are listed here.

- 1. A cylinder is not a good representation for the Earth if large lateral maneuvers are made. The accuracy of PRESTO II will, therefore, fall off as the size of the lateral maneuver increases.
- 2. The approximation concerning the $\frac{uv}{r}$ term in the equations of motion is not good when one stage goes from orbital speed to a high supercircular velocity. The program should not be used for interplanetary transfers requiring a large hyperbolic excess velocity. Program operation is satisfactory for lunar transfer missions.
- 3. When using the lunar landing mission option, the horizontal component of velocity must not be allowed to go negative. This can happen if a poor nominal is used or if the stopping parameter is too close to zero. Interpolation to the correct stopping condition fails when the velocity goes negative.
- 4. When the total time constraint option is used, the weighting function associated with the final coast stage must be set to a large number, e.g., 10⁸.

5. DERIVATION AND PROGRAMMING OF OPTIMIZATION EQUATIONS

The optimization procedure used in PRESTO II is similar to that used in PRESTO. The major differences are:

- 1. The thrust orientation angles are now discrete rather than continuous; therefore no integral terms appear.
- 2. The calculation for new controls is made only once at the beginning of a trajectory. There is no closed-loop calculation as in PRESTO.
- 3. The sensitivity of terminal constraints to a change in a control is determined by perturbing the control and then comparing the perturbed terminal constraint with the nominal value. This process replaces the backward integration runs in PRESTO.

The fundamental relation is

$$d\Psi = Kde + Ldm;$$
 (1)

where

 $d\Psi$ is the terminal constraint vector

de is the control vector

dm; is the perturbation in launch mass

- K is a matrix of sensitivities, or influence coefficients
- L is a vector of influence coefficients for launch mass perturbations

A trajectory terminates when a stopping parameter, S, is satisfied. The influence of the controls and the launch mass on the stopping parameter is represented by the equation

It is not efficient to interpolate to the correct value of the stopping parameter when perturbing the controls. The reason for this is that each attempt at interpolation requires the same computation that is made to integrate the motion for the entire stage. Therefore, the sensitivity matrices will be evaluated for a fixed value of the mass ratio, ? They will then be converted to sensitivities with respect to a fixed stopping parameter. The subscripts ? and S will be used to indicate whether the matrix refers to a fixed mass ratio or fixed stopping parameter condition.

The following equations relate terminal perturbations at a fixed stopping parameter to the perturbations at a fixed mass ratio.

$$d\Psi|_{S} = d\Psi|_{p} + \Psi'|_{p} dS \tag{3}$$

$$dS|_{S} = dS|_{S} + S'|_{S} dS \tag{4}$$

where
$$\Psi' = \frac{d\Psi}{dS}$$
; $S' = \frac{dS}{dS}$

and Af is the change in the nominal mass ratio required to meet the stopping condition in the presence of a control perturbation.

By definition, $dS|_{S^2}$ 0. Solving Eq. 4 for dS, one obtains

$$dS = -\frac{dS|_{9}}{S'} \tag{5}$$

Substitute Eq. 5 into Eq. 3 to obtain

$$d\Psi|_{S} - d\Psi|_{9} - \frac{\Psi'}{S'} dS|_{9} \tag{6}$$

Eqs. 1 and 2 are to be evaluated for fixed mass ratios. Using the proper subscripts, substitute then into Eq. 6 to obtain

$$d\Psi|_{S} = K_{S}de + L_{S}dm_{i} \tag{7}$$

where

$$K_{S} = K_{g} - \frac{\psi'}{g'} M_{g}$$

$$L_{S} = L_{g} - \frac{\psi'}{g'} N_{g}$$

It is now desired to find the vector $\mathbf{d}_{\mathbf{c}}$ which will produce a desired change $\mathbf{d}\Psi|_{\mathbf{g}}$ in the presence of a launch mass change $\mathbf{d}\mathbf{m}$. Furthermore, a weighted sum of the squares of the changes in the control parameters should be minimized, i.e., one desires to minimize

while satisfying Eq. 7. Z is a diagonal matrix of weighting functions. Use Lagrange multipliers to form the quantity

$$V = de^{\mathsf{T}} \mathsf{Z} de + \mu (d\Psi |_{S} - \mathsf{K}_{S} de - \mathsf{L}_{S} dm_{i})$$
 (8)

Write the first order perturbation equation for V

$$\delta V = (2 d e^{T} Z - \mu K_{g}) \delta(de)$$
 (9)

 \S V must be zero for arbitrary changes in $d\epsilon$. The coefficient of $\S(d\epsilon)$ must therefore be zero. Solving for $d\epsilon$ gives the following result.

$$de = \frac{z^{-1} K_{g}^{T} \mu^{T}}{2}$$
 (10)

To determine μ , substitute Eq. 10 into Eq. 7.

$$\mu^{\mathsf{T}} = 2\left(\mathsf{K}_{\mathsf{S}} \; \mathsf{Z}^{\mathsf{T}} \; \mathsf{Z}_{\mathsf{S}}^{\mathsf{T}}\right)^{\mathsf{T}} \left(\mathsf{d} \; \mathsf{Y} \; \mathsf{S} \; - \; \mathsf{L}_{\mathsf{S}} \; \mathsf{d} \; \mathsf{m}_{\mathsf{I}}\right) \tag{11}$$

Substitute Eq. 11 into Eq. 10 to obtain

$$de = Z' K_s^T (K_s Z' K_s^T)' (d\Psi|_s - L_s dm_i)$$
 (12)

In the program, the following notation has been used

$$K_g = \emptyset KZ$$
 $L_g = \emptyset LZ$
 $L_g = \emptyset LZ$
 $M_g = \emptyset MZ$
 $M_g = \emptyset MS$
 $M_g = \emptyset MS$

 K_9 , L_9 , M_9 , N_9 , Ψ' , and S' are evaluated in the PERTRB subroutine. K_9 and M_9 are determined by perturbing the controls, one by one, and observing the effect on the terminal constraints.

Ly and Ny are determined in the same way with the launch mass perturbed. Ψ' and S' are evaluated by perturbing the mass ratio of the final stage.

 K_s , L_s , M_s and N_s are computed in the MEQ2 subroutine. AA is formed and inverted and substituted back into AA. ZKA and ZKAL are then formed.

ZINV is computed at the start of the main program. The actual computation of the change in the control vector (Eq. 12) is made in the CONC subroutine in the form

$$DCQN = ZKAdV - ZKALdm; (13)$$

where DCON is the program symbol for de.

OPTIMIZATION SUCCESS CRITERION

The optimization success criterion is identical to that used in PRESTO. Only the notation has been changed. Thus, Eq. 1 on page 8-14a in the PRESTO report becomes

$$dm_{f} = PPAY_{1} dm_{i} + \sum_{j=2}^{3c} PPAY_{j} dV_{j}$$
(14)

An optimization run is successful if the terminal constraints are sufficiently close to the desired values and if

$$(m_f + dm_f)_{\text{current run}} > (m_f + dm_f)_{\text{LAST RUN}}$$
 (15)

where
$$dm_{c} = \sum_{j=2}^{3c} PPAY_{j} dV_{j}$$
 for the fixed launch weight option

and
$$d_{m_f} = \begin{cases} \frac{5}{5} \text{ PPAY}_1 dV_1 + \text{PPAY}_1 (DWFUEL/9.) \end{cases} (1 - \text{PPAY}_1)^{-1}$$

for the fixed final stage option.

SELECTION OF MASS IMPROVEMENT

The selection of mass improvement differs from PRESTO in that the improvement to be asked for is recomputed after every successful run using the relation

$$dm_{NOM} = \sqrt{\frac{dP^2}{A_{II}}}$$
 (16)

 dm_{NOM} is then added to dm_f to obtain $d\Psi_i$, which is the actual change in final mass requested. If a run is unsuccessful, dm_{NOM} is cut in half. In the output, DMASD still indicates the first computation of dm_{NOM} made after a successful guidance run.

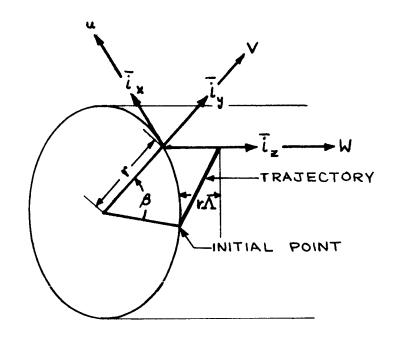

6. EQUATIONS OF MOTION

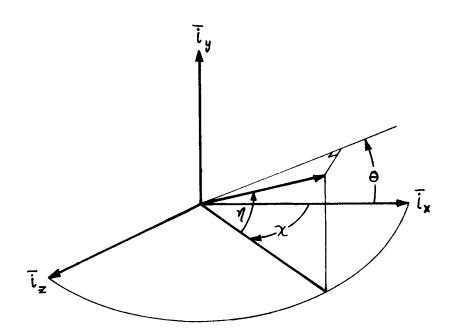

AN APPROXIMATE SOLUTION TO THE THREE-DIMENSIONAL EQUATIONS OF MOTION OUTSIDE OF THE ATMOSPHERE

If motion is restricted to the vicinity of a great circle defined by the initial velocity vector, it is reasonable to represent the Earth as a cylinder. On a cylindrical Earth, motion in the longitudinal and lateral directions is uncoupled. Longitudinal motion may be described in the usual polar coordinate system while the lateral motion takes place under the assumption that the Earth is flat.

The coordinate system used in PRESTO II is shown on the next page. The initial velocity vector lies in the \overline{i}_x - \overline{i}_y plane. The \overline{i}_x axis is along the local horizontal and the \overline{i}_y axis lies along the radius vector. u, v, and w are the components of velocity along the \overline{i}_x , \overline{i}_y , and \overline{i}_z axes, respectively. β is the in-plane range angle. Λ is the out-of-plane distance divided by the radius.

The thrust orientation angles are illustrated on the next page. θ is the angle between the \overline{i}_x axis and the component of thrust in the \overline{i}_x - \overline{i}_y plane. X is the angle between the \overline{i}_x axis and the component of thrust in the \overline{i}_x - \overline{i}_z plane. η is the angle between the thrust vector and the local horizontal. It is related to the two control angles by the Equation:

DIAGRAMS OF COORDINATE SYSTEM AND THRUST ORIENTATION ANGLES

$$tan \eta = tan \theta \cos \chi \tag{1}$$

With lift and drag neglected, the equations of motion are:

$$\dot{u} = \frac{T}{m} \cos \eta \cos \chi \, sgn \, \xi - \frac{uv}{r} \tag{2}$$

$$\dot{v} = \frac{T}{m} \sin \eta \, sgn \, \xi - q + \frac{u^2}{r} \tag{3}$$

$$\dot{w} = \frac{T}{m} \cos \eta \sin \chi \, sgn \, \xi \tag{4}$$

$$\dot{\beta} = \frac{u}{r} \tag{5}$$

$$\dot{\mathbf{r}} = \mathbf{v}$$
 (6)

$$\dot{\Lambda} = \frac{W}{r} \tag{7}$$

$$\dot{m} = -\frac{T}{c} \tag{8}$$

Sgn ξ is normally +1. It is set to -1 for retroburns because θ and χ are limited to ± 90 degrees.

It will be convenient to use the mass ratio, instead of time, as the independent variable. The mass ratio is defined as:

$$\mathcal{I} = \frac{m}{m_i} \tag{9}$$

where M_i is the mass at the beginning of a stage. The time derivative of β is:

$$\frac{d\hat{S}}{dt} = -\frac{T}{m_i^c} \tag{10}$$

With the help of Eq. 10, the equations of motion are converted to:

$$\frac{du}{d\theta} = -\frac{c \cos \eta \cos \chi \operatorname{sgn} \xi}{\theta} + \frac{m_i c}{Tr} uv \tag{11}$$

$$\frac{dv}{d\hat{y}} = -\frac{c \sin \eta \, sgn \, \xi}{\hat{y}} - \frac{m_i c}{T} \frac{u^2}{r} + \frac{g \, m_i c}{T} \tag{12}$$

$$\frac{dw}{d\theta} = -\frac{c \cos \eta \sin \chi \, sgn \, \xi}{\theta} \tag{13}$$

$$\frac{d\beta}{d\beta} = -\frac{m_i c}{T} \frac{u}{r} \tag{14}$$

$$\frac{dr}{d\theta} = -\frac{m_i c}{T}$$
 (15)

$$\frac{d\Lambda}{d\theta} = -\frac{m_{ic}}{T} \frac{w}{r} \tag{16}$$

$$\frac{dm}{d\beta} = m_{i} \tag{17}$$

where c is the exhaust velocity.

The two thrust orientation angles, Θ and χ , are to vary in accordance with the "linear-tangent" law; i.e.,

$$tan \theta = a + bt (18)$$

$$tan \chi = e + ft$$
 (19)

a, b, e, and f are constants.

Using the relation $m = m_i - \frac{T}{c} t \tag{20}$

one can write

$$tan \theta = A + B$$
 (21)

$$tan \chi = E + F$$
 (22)

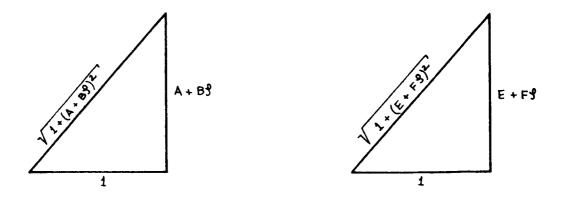

where $A = a + \frac{bc m_i}{T}$ $E = e + \frac{fc m_i}{T}$ $B = -\frac{bc m_i}{T}$ $F = -\frac{fc m_i}{T}$

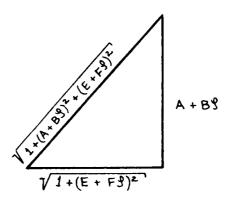

With the aid of the following three triangles, the trigonometric terms in the equation of motion can be written as:

$$\cos \eta \cos \chi = \frac{1}{\sqrt{1 + (A + B^{g})^{2} + (E + F^{g})^{2}}}$$
 (23)

$$\sin \eta = \frac{A + B^2}{\sqrt{1 + (A + B^2)^2 + (E + F^2)^2}}$$
 (24)

$$\cos \eta \sin \chi = \frac{E + F^{3}}{\sqrt{1 + (A + B^{3})^{2} + (E + F^{3})^{2}}}$$
 (25)

The equation for the horizontal component of velocity (Eq. 11) is first integrated with the term containing uV neglected. One has,

$$u_t - u_i = -c \operatorname{sgn} \xi \int_{f} \frac{d\vartheta}{\int \sqrt{1 + (A + B\vartheta)^2 + (E + F\vartheta)^2}}$$

After integration, one obtains

$$u_{t} - u_{i} = \frac{c \, sgn \, \xi}{\sqrt{1 + A^{2} + E^{2}}} \times$$
 (26)

where

$$X = \ln \left[\frac{\sqrt{1 + (A + B_{x}^{2})^{2} + (E + F_{x}^{2})^{2}} \sqrt{1 + A^{2} + E^{2}} + 1 + A(A + B_{x}^{2}) + E(E + F_{x}^{2})}{\sqrt{1 + (A + B)^{2} + (E + F)^{2}} \sqrt{1 + A^{2} + E^{2}} + 1 + A(A + B) + E(E + F)} \frac{1}{g_{x}} \right]$$

For β , one has

$$\beta_{f} - \beta_{i} = -\frac{m_{i}c}{Tr} \int_{1}^{1} u \, d\vartheta = -\frac{m_{i}c}{Tr} \int_{1}^{1} \left[u_{i} + \int_{1}^{1} \frac{du}{d\vartheta} \, d\vartheta \right] d\vartheta$$

$$= -\frac{m_{i}c}{Tr} u_{i} (\beta_{f} - 1) - \frac{m_{i}c}{Tr} \int_{1}^{1} \int_{1}^{1} \frac{du}{d\vartheta} \, d\vartheta \, d\vartheta$$

The double integral is evaluated with the help of the relation

$$\int_{\lambda}^{1} \int_{\lambda}^{1} + (\lambda) \gamma = \int_{\lambda}^{1} (\lambda^{t} - \lambda) + (\lambda) \gamma$$
(54)

Using Eq. 27, one obtains:

$$\beta_{f} - \beta_{i} = -\frac{m_{ic}}{Tr} \left[\beta_{f} (u_{f} - u_{i}) + u_{i} (\beta_{f} - 1) + \frac{c \operatorname{sgn} \xi}{\sqrt{B^{2} + F^{2}}} Y \right]$$
 (28)

where

$$Y = \ln \frac{\sqrt{1 + (A + B_{f}^{2})^{2} + (E + F_{f}^{2})^{2} + \sqrt{B^{2} + F^{2}}} \frac{AB + EF}{\sqrt{B^{2} + F^{2}}}}{\sqrt{1 + (A + B)^{2} + (E + F)^{2} + \sqrt{B^{2} + F^{2}}} + \frac{AB + EF}{\sqrt{B^{2} + F^{2}}}}$$

If B and F are both zero, the last term in Eq. 28 is:

$$\frac{c(\hat{S}_{f}-1) \operatorname{sgn} \xi}{\sqrt{1+A^{2}+E^{2}}}$$

In order to integrate the equation for vertical velocity, an integrable expression for u^2 must be found. The approach used here is to split the logarithmic term for u into two parts and then to expand the second term in a series in $\mathcal G$. One can write

(27)

$$u = u_i + \frac{c.agn\xi}{\sqrt{1 + A^2 + E^2}} \left[ln \frac{1}{9} + ln \left(\frac{1 + A(A+BS) + E(E+FS) + \sqrt{1 + A^2 + E^2} \sqrt{1 + (A+BS)^2 + (E+FS)^2}}{1 + A(A+B) + E(E+F) + \sqrt{1 + A^2 + E^2} \sqrt{1 + (A+B)^2 + (E+F)^2}} \right]$$

Note that if the slopes of the control angles are equal to zero, the second \ln term is equal to zero. Furthermore, when B and F are not zero, numerical checks for reasonable control angles indicate that the term in the round brackets does not move very far from unity. Write the term in the round brackets as N/D, where N and D are numerator and denominator, respectively. Then:

$$ln\left(\frac{N}{D}\right) = ln\left(\frac{D+Z}{D}\right) = ln\left(1+\frac{Z}{D}\right) \approx \frac{Z}{D}$$

assuming N/D is close to unity. Using the approximation

$$\sqrt{1+\alpha'} \approx 1 + \frac{\alpha}{2}$$

one obtains for Z the equation:

$$Z = (1 + \sqrt{1 + A^2 + E^2}) (AB + EF) (3-1) + \frac{\sqrt{1 + A^2 + E^2}}{2} (B^2 + F^2) (3-1)$$
 (30)

u can then be written as

$$u = u_i + \frac{c \operatorname{sgn} \xi}{\sqrt{1 + A^2 + E^2}} \operatorname{ln} \left[\frac{1}{9} + \frac{z}{D} \right]$$
(31)

After collecting terms, one has

$$u = A_1 + A_2 \ln^3 + A_3 + A_4 + A_4 + A_5 + A_$$

where

$$A_1 = u_1 - \frac{a_1(a_2 + a_3)}{a_4}$$

$$A_3 = \frac{a_1 a_2}{a_4}$$

$$A_{1} = \frac{a_1 a_3}{a_4}$$

and

$$\mathbf{a}_1 = \frac{c \operatorname{sgn} \xi}{\sqrt{1 + A^2 + E^2}}$$

$$a_{2} = (1 + \sqrt{1 + A^{2} + E^{2}})(AB + EF)$$

$$a_{3} = \frac{\sqrt{1 + A^{2} + E^{2}}(B^{2} + F^{2})}{2}$$

$$a_{4} = 1 + A(A + B) + E(E + F) + \sqrt{1 + A^{2} + E^{2}}\sqrt{1 + (A + B)^{2} + (E + F)^{2}}$$

U² is now readily integrable. Eq. 12 becomes:

$$\frac{dv}{d\theta} = -\frac{c(A+B^{\frac{2}{3}})}{\sqrt[3]{1+(A+B^{\frac{2}{3}})^{2}+(E+F^{\frac{2}{3}})^{2}}} + \frac{\sqrt[3]{m_{1}c}}{T} + B_{1} + B_{2}^{3} + B_{3}^{2} + B_{4}^{3} + B_{5}^{3} + B_{5}^{3}$$

where

$$B_{1} = KA_{1}^{2}$$

$$B_{2} = 2KA_{1}A_{3}$$

$$B_{5} = KA_{4}^{2}$$

$$B_{8} = 2KA_{2}A_{3}$$

$$B_{9} = 2KA_{2}A_{4}$$

Integration of Eq. 33 yields:

$$v_{f} - v_{i} = \frac{c A sgn \xi}{\sqrt{1 + A^{2} + E^{2}}} X - \frac{c B sgn \xi}{\sqrt{B^{2} + E^{2}}} Y + \frac{9 m_{i} c}{T} (J_{f} - 1) + P$$
 (34)

where

$$P = B_{1}(\beta_{f}-1) + \frac{B_{2}}{2}(\beta_{f}^{2}-1) + \frac{B_{3}}{3}(\beta_{f}^{3}-1) + \frac{B_{4}}{4}(\beta_{f}^{4}-1) + \frac{B_{5}}{5}(\beta_{f}^{5}-1) + B_{6}[\beta_{f}(\ln\beta_{f}-1)+1] + B_{7}[\beta_{f}(\ln\beta_{f})^{2}-2\beta_{f}\ln\beta_{f}+2\beta_{f}-2] + B_{8}[\frac{1}{2}\beta_{f}^{2}(\ln\beta_{f}-\frac{1}{2})+\frac{1}{4}] + B_{9}[\frac{1}{3}\beta_{f}^{2}(\ln\beta_{f}-\frac{1}{3})+\frac{1}{9}]$$

Using Eq. 27 once again, the equation for | is integrated to give:

$$\begin{split} r_{f} - r_{i} &= \frac{-m_{i}c}{T} \left[\int_{f}^{g} (V_{f} - V_{i}) + V_{i} (J_{f} - 1) + \frac{c F (AF - BE)}{(B^{2} + F^{2})^{3/2}} \right. \\ &+ \frac{c B Agn \xi}{B^{2} + F^{2}} \left(\sqrt{1 + (A + BJ_{f}^{2})^{2} + (E + FJ_{f}^{2})^{2}} - \sqrt{1 + (A + B)^{2} + (E + F)^{2}} \right) \\ &- \frac{B_{1}}{2} \left(J_{f}^{2} - 1 \right) - \frac{B_{2}}{3} \left(J_{f}^{3} - 1 \right) - \frac{B_{3}}{4} \left(J_{f}^{4} - 1 \right) - \frac{B_{4}}{5} \left(J_{f}^{5} - 1 \right) - \frac{B_{5}}{6} \left(J_{f}^{6} - 1 \right) \\ &- \frac{B_{6}}{2} \left[J_{f}^{2} \left(ln J_{f} - \frac{1}{2} \right) + \frac{1}{2} \right] - \frac{B_{7}}{2} \left[J_{f}^{2} \left(ln J_{f}^{6} \right)^{2} - ln J_{f}^{4} + \frac{1}{2} \right] - \frac{1}{2} \right] \\ &- \frac{B_{8}}{3} \left[J_{f}^{3} \left(ln J_{f} - \frac{1}{3} \right) + \frac{1}{3} \right] - \frac{B_{9}}{4} \left[J_{f}^{4} \left(ln J_{f} - \frac{1}{4} \right) + \frac{1}{4} \right] \\ &- \frac{m_{i} c g}{2 T} \left(J_{f}^{2} - 1 \right) \right] \end{split}$$

$$(35)$$

If B and F are zero, the term containing Y becomes:

$$\frac{c A sgn \xi (f_{f}-1)}{\sqrt{1 + A^2 + E^2}}$$

In a similar manner, the equations for w and Λ are integrated to give:

$$W_{f} - W_{i} = \frac{cE sqn \xi}{\sqrt{1 + A^{2} + E^{2}}} \chi - \frac{cF sqn \xi}{\sqrt{B^{2} + E^{2}}} \gamma$$
 (36)

$$\Lambda - \Lambda_{i} = -\frac{m_{i}c}{T_{F}} \left[J_{f}(w_{f} - w_{i}) + \frac{eB(BE - AF) sgn \xi}{(B^{2} + F^{2})^{3/2}} \right]$$

$$+ \frac{cF sgn \xi}{B^{2} + F^{2}} \left(\sqrt{1 + (A + BJ_{f})^{2} + (E + FJ_{f})^{2}} - \sqrt{1 + (A + B)^{2} + (E + FJ_{f})^{2}} \right) + w_{i}(J_{f} - 1)$$
(37)

If B and F are zero, the term containing Y becomes:

$$\frac{c \in Agn \notin (J_{+}-1)}{\sqrt{1+A^{2}+E^{2}}}$$

It will be recalled that the term containing uv in the differential equation for horizontal velocity was neglected. The influence of this term is accounted for in an approximate manner by adding to u_{ξ} the average value of $\frac{m_i c}{T_{\tau}}uv$ multiplied by the interval of integration. This additional term is:

$$\frac{m_{ic}}{2Tr} \left(u_i v_i + u_f v_f\right) \left(\frac{3}{5} - 1\right)$$

This approximate solution to the equations of motion is repeated for each powered stage with the final conditions at the end of the first stage becoming the initial conditions for the second stage. If a

coast precedes a powered stage, the axis of the cylinder is rotated so that there is no lateral motion at the beginning of the powered state; i.e., Λ_i and w_i are set to zero.

The value of r that is used in the solutions is obtained by averaging the initial and final radius for a stage on the last iteration.

• is computed using this average value of r.

CONVERSION FROM CYLINDRICAL TO GEOGRAPHIC COORDINATES

At the end of each powered stage, it is necessary to determine the position and velocity of the vehicle with respect to the spherical Earth.

This computation is done in the CONVRT subroutine.

At the beginning of the first control segment and after each coast we have available the inertial azimuth, $\Psi_{\rm I}$, the latitude, λ , and the longitude, $\mathcal T$. At the end of each powered stage, we know u, \vee , w, β , and Λ . It is necessary to compute inertial velocity, $V_{\rm I}$, inertial flight path angle, $\mathcal T_{\rm I}$, inertial azimuth, latitude and longitude.

Except for the symbols mentioned above, the terminology used in this subroutine is not related to the rest of the program.

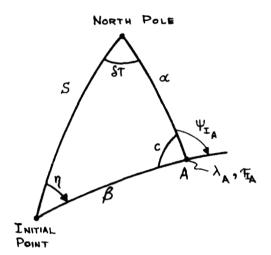

Inertial velocity is easily found from the Equation:

$$V_{T} = V u^2 + V^2 + W^2$$
 (1)

Inertial flight path angle is found from:

$$\mathcal{J}_{I} = \tan^{-1} \frac{\vee}{\sqrt{\mu^2 + W^2}} \tag{2}$$

Spherical trigonometry is required to determine the remaining variables. Consider the following triangle:

The computation is broken into two parts. We first determine the latitude and longitude at point A which is on the great circle defined by the initial velocity vector. η takes on one of two values depending on Ψ_{L} at the initial point:

If
$$\Psi_{\rm I} < \pi$$
 , $\eta = \Psi_{\rm I}$

If
$$\Psi_{\rm L} > \pi$$
, $\eta = 2\pi - \Psi_{\rm L}$

$$S = \frac{11}{2} - \lambda$$

Using spherical trigonometry, one obtains:

$$\cos \alpha = \cos S \cos \beta + \sin S \sin \beta \cos 7 \tag{1}$$

$$\frac{\sin \alpha}{\sin \eta} = \frac{\sin \beta}{\sin \delta \tau} \tag{2}$$

Compute $\sin \alpha$ from (1) as:

$$\sin \alpha = \sqrt{1 - \cos^2 \alpha} \tag{3}$$

Use Eqs. (1) and (3) to compute:

$$\alpha = \tan^{-1}\left(\frac{\sin\alpha}{\cos\alpha}\right) \tag{4}$$

If
$$\tan \alpha > 0$$
, $0 < \alpha < \frac{\pi}{2}$

If
$$\tan \alpha < 0$$
, $\frac{\pi}{2} < \alpha < \pi$

Knowing α , solve for $\sin \delta T$

$$\sin \delta T = \frac{\sin \eta \sin \beta}{\sin \alpha} \tag{5}$$

Then,
$$\cos \delta T = \sqrt{1 - \sin^2 \delta T}$$

and
$$ST = tan^{-1} \left(\frac{\sin ST}{\cos ST} \right)$$
 (6)

ST is always assumed to be less than $\pi/2$.

The latitude at point A, λ_A , is:

$$\lambda_{\mathbf{A}} = \frac{\pi}{2} - \alpha \tag{7}$$

and the longitude is:

$$T_{A} = T_{I} \pm ST$$
+ if $\Psi_{I} < \pi$
- if $\Psi_{I} > \pi$

Knowing \mathfrak{ST} , one can solve for c using

$$\cos c = -\cos \delta T \cos \eta + \sin \delta T \sin \eta \cos S$$

$$\sin c = \sqrt{1 - \cos^2 c}$$
(8)

and

$$c = \tan^{-1}\left(\frac{\sin c}{\cos c}\right) \tag{9}$$

If
$$tanc > 0$$
 $0 < c < \frac{\pi}{2}$

If
$$\tan c < 0$$
 $\frac{\pi}{2} < c < \pi$

Then

$$\Psi_{\mathbf{r}_{\mathbf{A}}} = \pi - \mathbf{c} \tag{10}$$

The inertial azimuth at the end of a stage also depends upon the outof-plane velocity, w. Let

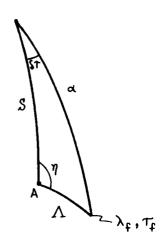

$$d = \tan^{-1}\left(\frac{W}{c}\right) \tag{11}$$

The inertial azimuth is then found from:

$$\psi_{t} = \psi_{I_{A}} + d \qquad \text{If } \psi_{I} > \pi$$

$$\psi_{t} = 2\pi - \psi_{I_{A}} + d \qquad \text{If } \psi_{I} > \pi$$
(12)

The second part of the calculation is similar to the first except that Λ replaces eta .

Define an angle m as follows:

$$m = \psi_{I_A} + \frac{\pi}{2} sgn d$$
 if $\psi_I < \pi$

$$m = 2\pi - \psi_{I_A} + \frac{\pi}{2} sgn d$$
 if $\psi_I > \pi$

If $m > 2\pi$, subtract 2π from it.

Define 1/ as follows:

$$\eta = m$$

if m< T

$$\eta = 2\pi - m$$

11 m > 17

$$S = \frac{\pi}{2} - \lambda_{A}$$

and

$$\cos \alpha = \cos S \cos \Lambda + \sin S \sin \Lambda \cos \eta$$

$$\sin \alpha = \sqrt{1 - \cos^2 \alpha}$$
(13)

$$d = \tan^{-1}\left(\frac{\sin \alpha}{\cos \alpha}\right)$$

Use the quadrant check that follows Eq. 4:

Then

$$\sin ST = \frac{\sin \eta \sin \Lambda}{\sin \alpha} \tag{14}$$

$$\cos ST = \sqrt{1 - \sin^2 ST}$$

and

$$\delta T = \tan^{-1} \left(\frac{\sin \delta T}{\cos \delta T} \right) \tag{15}$$

The latitude at the end of the stage is:

$$\lambda_{f} = \frac{\pi}{2} - \alpha \tag{16}$$

and the longitude is:

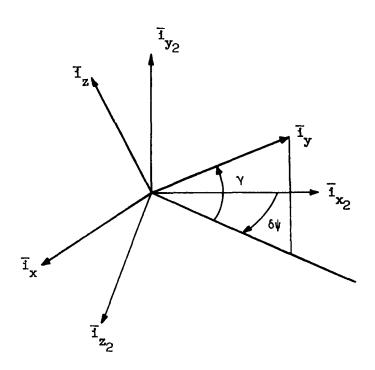

$$T_{f} = T_{T_{A}} - \omega \Delta t \pm ST$$

$$- if m > \pi$$

where At is the time from the initial point.

At the end of the PRESTO II iteration, we have two control angles, θ_2 and χ_2 , defined with respect to the PRESTO II coordinate system. It is necessary to convert these angles to the PRESTO control angles, η and χ , for use in generating the initial integrated trajectory.

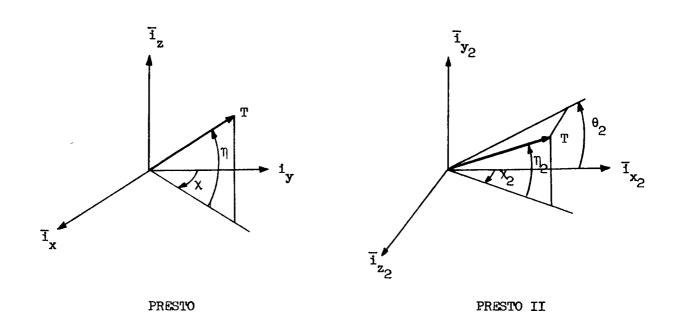

The two coordinate systems are related as shown in the following diagram. The subscript 2 refers to the PRESTO II system. γ is the flight path angle.

δψ is the angle between the great circle path defined by the initial velocity vector in the PRESTO II system and the horizontal component of velocity in

the PRESTO system. The lateral motion in the PRESTO II system, described by the angle Λ is assumed to be small. This leads to the approximation that the $\overline{1}_z$ and $\overline{1}_{y_2}$ axes are parallel when γ is zero.

The orientation of the thrust vector in the two coordinate systems is shown below.

The thrust vector in the PRESTO II system is resolved into components to give

$$\overline{T} = T \left[\overline{i}_{x_2} T_{x_2} + \overline{i}_{y_2} T_{y_2} + \overline{i}_{z_2} T_{z_2} \right]$$
 (1)

where
$$T_{x_2} = \cos T_2 \cos x_2$$

 $T_{y_2} = \sin T_2$
 $T_{z_2} = \cos T_2 \sin x_2$
and $\tan T_2 = \tan \theta_2 \cos x_2$

The components of thrust in the PRESTO II system, resolved along the PRESTO coordinates, is given by

$$\overline{T} = T \left\{ \overline{I}_{x} \left[-T_{x_{2}} \sin \delta \psi + T_{z_{2}} \cos \delta \psi \right] + \overline{I}_{y} \left[T_{x_{2}} \cos \delta \psi \cos \gamma + T_{y_{2}} \sin \gamma \right] + T_{z_{2}} \sin \delta \psi \cos \gamma \right\} + \overline{I}_{z} \left[-T_{x_{2}} \cos \delta \psi \sin \gamma + T_{y_{2}} \cos \gamma \right] + T_{z_{2}} \sin \delta \psi \sin \gamma \right\}$$

$$\left\{ -T_{z_{2}} \sin \delta \psi \sin \gamma \right\}$$

$$\left\{ (2) \right\}$$

The components of thrust in the PRESTO system, resolved along the PRESTO coordinates, is given by

$$\overline{T} = T \left[\overline{i}_{x} \cos \eta \sin \chi + \overline{i}_{y} \cos \eta \cos \chi + \overline{i}_{z} \sin \eta \right]$$
(3)

The coefficients of the unit vectors in Eqs. 2 and 3 must be equal. One obtains

$$\sin \eta = -T_{x_2} \cos \delta \psi \sin \gamma + T_{y_2} \cos \gamma - T_{z_2} \sin \delta \psi \sin \gamma$$
 (4)

$$\cos \eta = \sqrt{1 - \sin^2 \eta} \tag{5}$$

$$\eta = \tan^{-1}\left(\frac{\sin\eta}{\cos\eta}\right) \tag{6}$$

and

$$\sin \chi = \frac{1}{\cos \eta} \left[-T_{x_2} \sin \delta \psi + T_{z_2} \cos \delta \psi \right]$$
 (7)

$$\cos \chi = \sqrt{1 - \sin^2 \chi} \tag{8}$$

$$\chi = \tan^{-1}\left(\frac{\sin\chi}{\cos\chi}\right) \tag{9}$$

These calculations are made in the PCAL subroutine.

The angle of is computed as

$$\delta \psi = \psi - \psi_{\rm p} \tag{10}$$

where ψ is the local azimuth and ψ_R is the instantaneous azimuth along the great circle defined by the initial inertial velocity vector. ψ_R is computed after every step of integration using the relation

$$\psi_{R_n} = \psi_{R_{n-1}} + \dot{\psi}_R (DT) \tag{11}$$

where

$$\dot{\psi}_{R} = \frac{V_{I} \cos \gamma_{I} \sin \psi_{R} \sin \lambda}{r \cos \lambda}$$

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

-National Aeronautics and Space Act of 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Technical information generated in connection with a NASA contract or grant and released under NASA auspices.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

TECHNICAL REPRINTS: Information derived from NASA activities and initially published in the form of journal articles.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities but not necessarily reporting the results of individual NASA-programmed scientific efforts. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

Details on the availability of these publications may be obtained from:
